Summary

I build software that decides which AI model can handle a request, keeps market data in sync, and checks trading risk. I work in Python and TypeScript, with a focus on clear rules and failures I can reproduce.

Selected public work

verdict-node · Request checks for Node.js apps

Brings request checks into Express and Next.js apps. The middleware checks outgoing OpenAI-compatible requests at the HTTP boundary rather than relying on each caller to apply the rules.

Project status: Published as an alpha. The shared Python/TypeScript request contract is still being aligned; end-to-end enforcement is not complete.

TypeScript · Express · Next.js · Zod

Verdict · Choosing models within limits

Model routing with rules that ranking cannot override. Verdict checks capability, privacy, reliability, and policy first, then ranks only the models that qualify.

Project status: Try routing and simulated failures without API keys. The demo uses fixtures, not live providers.

Python · policy gates · receipts · failover

Prediction Market SDK · Keeping market data in sync

A typed, async Python SDK for Kalshi market data and orders. Reusable L2 order books track snapshots and deltas, while a WebSocket layer manages connections and subscriptions.

Project status: Kalshi signing, order workflows, and market-data handling are tested. Polymarket signing and live-order safeguards are still limited.

Python · AsyncIO · WebSockets · msgspec

Capabilities

Full stack

- TypeScript
- React
- Next.js
- Node.js
- Express
- Accessible UI

Backend & data

- Python
- AsyncIO
- FastAPI
- WebSockets
- SQLite
- Typed contracts

Platform engineering

- CI/CD
 - Contract parity
 - Security gates
 - Failure recovery
 - Reproducible testing
-

This project-based profile covers my public software work. Follow the repository links for implementation details and current limitations.
